Appendix A

1 In line with the Commission's VGI White Paper issued November 22, 2013,¹ my
2 testimony introduces a cost-effectiveness methodology for the Commission's consideration
3 to use in evaluating various VGI solutions, such as those proposed in SDG&E's VGI Pilot
4 Program. The methodology relies on an analytical model developed at my direction by
5 Energy and Environmental Economics (E3), a consulting firm that has conducted economic
6 assessments in support of the Commission's policy development in the area of distributed
7 energy resources including distributed generation, demand response, and energy efficiency.
8 The methodology and model described in my testimony builds upon standard cost-
9 effectiveness tests familiar to the Commission.

10 Cost-effectiveness methodology is used to model EV charging in SDG&E's service
11 territory under two sets of hypothesized assumptions, including assumptions on SDG&E's
12 VGI Pilot Program. Results are used to infer market level insights into the cost and benefits
13 of deploying EV charging at workplace and multi-unit dwelling (MuD) locations. The
14 model output is illustrative only and is not intended to be predictive. However, results may
15 provide policy makers with insights about various VGI solutions in the SDG&E EV
16 charging market. The results also may provide policy makers with a method to evaluate the
17 benefits of the VGI Pilot Program in general and the VGI Rate in particular.

18 The Research Plan described in my testimony provides a link between the
19 hypothesized assumptions and realized VGI Pilot Program results available upon completion
20 of the VGI Pilot Program. The Research Plan describes the data to be collected during the
21 VGI Pilot Program deployment and operation (e.g., costs and energy usage at VGI

¹ Available at: <http://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M080/K775/80775679.pdf>

1 facilities). As customer EV charging data and cost information becomes available through
2 the VGI Pilot Program deployment and operation, observed results will replace
3 hypothesized assumptions in order to more rigorously evaluate the cost-effectiveness of
4 SDG&E's completed VGI Pilot Program.

5 To illustrate the effect of the hourly time-variant VGI pricing on EV customer
6 charging decisions, two EV charging scenarios are hypothesized with two sets of
7 assumptions. Both scenarios represent a depiction of SDG&E's service territory EV
8 charging market. One scenario includes an EV charger deployment with the VGI Pilot
9 Program including the VGI Rate (VGI Rate scenario). The other scenario characterizes a
10 similar EV charger deployment as the VGI Pilot Program, but deployed by a non-utility
11 entity with EV charging priced as a flat rate or fee (Flat Rate scenario).

12 The Flat Rate scenario depicts an EV charging environment inspired by today's
13 options for EV customers. The VGI Rate scenario utilizes cost inputs described in Chapter
14 2 and the VGI Rate pricing described in Chapter 3. The Flat Rate scenario uses similar EV
15 charging technology installation and cost assumptions as the VGI Rate scenario and flat rate
16 pricing. The composition of the Flat Rate is further described in section II.B.3.

17 **II. COST EFFECTIVENESS MODELING**

18 The VGI Pilot Program supports state policy and law encouraging efforts which
19 increase the environmentally beneficial use of electricity as transportation fuel, described in
20 the testimony of Lee Krevat (Chapter 1).² The VGI Pilot Program goal is to explore ways to
21 improve the utilization of utility grid assets and energy resource availability for the benefit

² Witness Lee Krevat's testimony, Chapter 1.

1 of all customers.³ The successful implementation of a VGI solution (as SDG&E proposes)
2 is intended to result in increased electricity use and decreased fossil fuel use. The evaluation
3 methodology will quantify the costs and benefits of these impacts.

4 The cost-benefit methodology described in my testimony employs and adapts similar
5 analytical properties as methodologies currently in use to evaluate Energy Efficiency (EE),
6 Demand Response (DR), and Distributed Generation (DG) programs. EE and DR programs
7 are designed to reduce demand and energy use or shift electricity use to lower cost periods.
8 EE, DR and DG programs are traditionally evaluated based on their incremental costs and
9 benefits of discrete projects.⁴

10 Discrete project evaluation is less applicable for price-based EV charging programs,
11 due to the unique flexibility of EV charging decisions. An EV customer can choose when
12 (time of day), where (location), how quickly (kW), how long (duration) and how often
13 (frequency) to charge. For an EV customer, EV fuel prices at one location and at one time
14 will influence EV charging not only at that location and time, but also charging at other
15 locations and at other available times. To capture these interrelated location and charging
16 time dynamics, a market level approach (i.e., modeling all customer groups, vehicle types,
17 charging locations, and prices) is required to evaluate level load impacts and their
18 corresponding costs and benefits for a price-based EV charging program.

19 **A. Overview**

20 SDG&E hired E3 to develop a VGI Cost-Benefit model leveraging many of E3's
21 existing models already utilized in California energy policy analysis. Under my direction,

³ Alternative Fuel Vehicle Order Instituting Rulemaking, R.13-11-007.

⁴ See "California Standard Practice Manual," http://www.cpuc.ca.gov/NR/rdonlyres/004ABF9D-027C-4BE1-9AE1-CE56ADF8DADC/0/CPUC_STANDARD_PRACTICE_MANUAL.pdf (2001).

1 E3 performed analysis of SDG&E’s hypothesized set of market level assumptions
2 characterizing the proposed VGI Pilot Program, including the dynamic time-differentiated
3 VGI Rate for EV charging at workplace and MuD locations. The analysis was conducted in
4 three steps:

- 5 (1) Define market scenarios in terms of EV charging locations and pricing.
- 6 (2) Estimate aggregate market level load impacts for each scenario for each hour
7 of the day.
- 8 (3) Calculate the cost and benefit components associated with each scenario and
9 compile the results for the illustrative cost effectiveness tests.

10 **1. EV Market Scenarios**

11 This analysis models two SDG&E service territory wide EV market scenarios that
12 model EV charging for current and future EVs in the SDG&E service territory. The primary
13 differences between the two market scenarios is who owns the workplace and MuD EV
14 charging technology (SDG&E or a non-utility entity), and what prices are EV customers
15 exposed to at these charging locations (VGI Rate or Flat Rate).

16 **a. VGI Rate Scenario**

17 SDG&E-owned VGI charging technology installations at workplace and MuD
18 locations are deployed as described in this Application. EV customers are exposed to
19 dynamic time-variant prices (VGI Rate) while charging EVs at VGI installations. The VGI
20 Rate encourages grid-integrated EV charging based on the dynamic hourly price that reflects
21 grid supply and demand conditions. (VGI Rate modeling is discussed in section II.B.4).

b. Flat Rate Scenario

A Non-Utility entity owns charging installations at workplace and MuD EV locations and deploys them under similar assumptions as the VGI Rate scenario. EV customers are exposed to Flat Rate prices while charging EVs in these locations. (The Flat Rate is described in section II.B.3).

2. Aggregate Market Level Load Impacts

Aggregate load impacts are estimated for each scenario to determine the hourly load and total usage (kW and kWh) for the entire SDG&E EV market. Aggregate load impacts are used as inputs to the VGI Cost-Benefit model. Customer behavior induced by EV charging prices is a key consideration in determining where and when EV charging occurs. EV charging load impacts are estimated under the assumption that EV customers desire to meet their EV driving requirements at the lowest available EV fuel prices. A cost optimization approach is used to estimate the price-induced EV charging behavior. This approach reflects the cost optimization built into the VGI Pilot Program technology and support system. The VGI system dispenses electricity at the lowest possible price within the EV charging customers' requirements, as explained in Mr. Schimka's testimony. This cost optimization process is discussed in section II.B.

3. VGI Cost-Benefit Model

The VGI Cost-Benefit Model estimates results for cost and benefit components used in the California Standard Practice Manual (standard) cost-effectiveness tests (e.g., as used

1 with EE and DR program evaluations).⁵ Aggregate load impacts are an important input to
2 the VGI Model because several of the cost-benefit test components use hourly energy values
3 as the basis for valuation. Once each test component is estimated, the standard cost-
4 effectiveness tests are calculated, specifically: the Ratepayer Impact Measure (RIM), the
5 Participant Cost Test (PCT), the Total Resource Cost (TRC), and the Societal Cost Test
6 (SCT). Table 6-1 lists the test components and their relationship to the cost-effectiveness
7 tests used in this analysis. The gray cells in table 6-1 indicate that a test component is not
8 applicable to a particular cost-effectiveness test. Test Components for the cost-effectiveness
9 tests are discussed in detail in section II.D below.

10

⁵ See "California Standard Practice Manual, available at http://www.cpuc.ca.gov/NR/rdonlyres/004ABF9D-027C-4BE1-9AE1-CE56ADF8DADC/0/CPUC_STANDARD_PRACTICE_MANUAL.pdf (2001).

2

3 B. Cost Optimization Approach to Estimate EV Charging Load Impacts

4 EV charging load impacts are necessary to value many of the test components listed
5 in Table 6-1 above. EV charging load impacts are estimated using a cost optimization
6 approach, which models EV charging behavior in response to different pricing signals at
7 different locations subject to EV mileage requirements and vehicle characteristics. The

1 following sections describe the inputs used in the cost optimization process and a description
2 of the approach. The section concludes with a description of how the aggregate EV
3 charging load impacts are estimated.

4 **1. EV Customer Groups, Mileage Requirements and Characteristics**

5 The cost optimization process, developed for the purposes of evaluating the VGI
6 Pilot Program, considers five groups of EV customers presented in Table 6-2. The EV
7 customer groups are defined by their residential location (either Single Family (SF) or MuD)
8 and by the availability of workplace EV charging (Unavailable, Preexisting, or New). Each
9 EV customer group has available charging locations, prices and Zero Emission Miles
10 (ZEM)⁶ driving requirements. ZEM is the number of miles traveled using electricity as
11 transportation fuel.

12 Available EV charging locations and prices are defined for each EV customer group
13 depending on the day of the week and time of day. During day hours on weekdays, EV
14 charging is assumed to be available at the workplace location (if available in the group), and
15 during night hours EV charging is assumed to be available at the residence location (either
16 SF or MuD). Weekend EV charging is assumed to occur exclusively at the residential
17 location.

⁶ Zero Emission Miles (ZEM) are also known as electric Vehicle Miles Traveled (eVMT).

Table 6-2

EV Customer Groups: Zero Emission Mile Requirements, EV Charging Locations and Prices							
EV Customer Groups			ZEM Required [2]	EV Charging Locations and Prices			
Group [1]	Residence Type	Workplace Charging Access		Charging Locations	Available Hours[3]	Available Prices	
			Flat Rate scenario			VGI Rate Scenario	
1	SF	Preexisting	"Base+" Weekday	Workplace	Day	Flat Rate	Flat Rate
				Residence	Night	Residential Rates	Residential Rates
			Weekend	Residence	All	Residential Rates	Residential Rates
2	SF	Unavailable	"Base" Weekday	N/A	Day	N/A	N/A
				Residence	Night	Residential Rates	Residential Rates
			Weekend	Residence	All	Residential Rates	Residential Rates
3	SF	New	"Base+" Weekday	Workplace	Day	Flat Rate	VGI Rate
				Residence	Night	Residential Rates	Residential Rates
			Weekend	Residence	All	Residential Rates	Residential Rates
4	MuD	Preexisting	"Base+" Weekday	Workplace	Day	Flat Rate	Flat Rate
				Residence	Night	Flat Rate	VGI Rate
			Weekend	Residence	All	Flat Rate	VGI Rate
5	MuD	Unavailable	"Base" Weekday	N/A	Day	N/A	N/A
				Residence	Night	Flat Rate	VGI Rate
			Weekend	Residence	All	Flat Rate	VGI Rate

[1] A Driver group with MuD and with new Workplace charging is not analyzed due to small size.

[2] Zero Emission Miles (ZEM) traveled for Driver Groups with Workplace charging is "Base+" which is greater than ZEM for groups without Workplace charging "Base". Workplace charging is assumed to provide additional EV charging for additional ZEM.

[3] Day hours are 8 AM to 5 PM , Night hours are 6 PM to 7 AM.

1 The mix of prices available at residence and workplace locations are different for
2 each EV customer group. Prices for all SF residential EV charging are assumed to be under
3 residential utility rates, (described in section II.B.2). Prices for all preexisting workplace EV
4 charging locations are assumed to be the Flat Rate, (described in section II.B.3). Customer
5 groups without workplace charging only have the option for EV charging at their residence.

6 The mix of prices differs for the two scenarios in three EV Charging Groups. Group
7 3 (SF residential charging and new workplace charging) has different prices available at the
8 workplace location (flat rate in the Flat Rate scenario and VGI Rate in the VGI Rate
9 scenario). Groups 4 and 5 have different prices at their MuD residence EV charging
10 location (flat rate in the Flat Rate scenario and VGI Rate in the VGI Rate scenario). Details
11 on the Flat Rate are described in section II.B.3. Details on the VGI Rate are described in
12 section II.B.4.

13 In addition to prices available at charging locations, each EV customer group has
14 required ZEM. Required ZEM is the number of electric miles needed by the EV customer
15 each day. Required ZEM mileage for each EV customer group is dependent on the
16 availability of workplace charging. Availability of workplace charging is assumed to
17 provide additional EV charging for additional weekday ZEM driving. Required ZEM is
18 defined as “Base” for EV customer groups without access to workplace charging, and
19 defined as “Base+” for groups with access to workplace charging. Weekend required ZEM
20 is not influenced by workplace EV charging, because weekend charging is assumed to occur
21 at the residence only. The number of ZEM electric miles required is specific to the type of
22 EV, as listed in Table 6-3.

Table 6-3

Required Zero Emission Mileage and EV Characteristics						
EV Type	"Base" Weekday required ZEM	"Base+" Weekday required ZEM	Weekend required ZEM	Battery Capacity (miles)	Watt Hours per Mile	EV Departure Min. SOC Required
BEV	30.8	31.9	26.2	< 100	350	30%
PHEV-10	10.0	20.0	10.0	10	350	30%
PHEV-20	20.0	31.9	20.0	20	350	30%
PHEV-40	31.9	31.9	27.2	40	350	30%
BEV = Battery Electric Vehicle w/ less than 100 mile range.						
PHEV-10 = Plug-in Hybrid Electric Vehicle w/ 10 mile EV range.						
PHEV-20 = Plug-in Hybrid Electric Vehicle w/ 20 mile EV range.						
PHEV-40 = Plug-in Hybrid Electric Vehicle w/ 40 mile EV range.						
ZEM = Zero Emission Miles. 31.9 miles is assumed maximum daily vehicles miles driven.						
SOC = battery's State of Charge.						
ICE = Internal Combustion Engine.						
[1] Incremental cost of EV vehicle relative to ICE vehicle is assumed to decrease over time by 10% per year.						

2

3 Table 6-3 lists required ZEM and EV characteristics for each EV type. The four EV
4 types include a Battery Electric Vehicle (BEV) (an all-electric vehicle) and three Plug-in
5 Hybrid Vehicles (PHEV) with different maximum EV ranges. "Watt Hours per Mile" is
6 used to convert the ZEM requirements from miles into kWh requirements for the cost
7 optimization process. Battery capacity for each EV type represents the maximum ZEM
8 ranges available when fully charged. EV departure minimum state of charge (SOC) is an
9 additional constraint used by the cost optimization process.

10 Single Family residential EV chargers are included in the analysis but are not
11 locations for VGI Pilot Program installations. Assumptions are made on the type of EV
12 charger that an EV customer uses at their SF residence. The type of charger in a SF

1 residence is determined by the EV-type battery capacity. A BEV and PHEV-40 is assumed
2 to have a Level 2 (L2) SF charger, and a PHEV-10 and PHEV-20 is assumed to have a
3 Level 1 (L1) SF. L1 chargers are assumed to have a 1.6 kW average charging capacity, and
4 L2 chargers a 3.5 kW average charging capacity.

5 Workplace and MuD EV charging is assumed to be 50% L1 and 50% L2 chargers, as
6 reflected in Mr. Schimka's testimony. The charger capacity assumption influences the
7 quantity of kWhs consumed at a particular location for a particular hour.

8 **2. Residential Rates**

9 Prices for SF residential EV charging are assumed to be a mixture of residential rates
10 available to SDG&E's EV customers. The residential rates considered are Schedule EV-
11 TOU-2 and Schedule DR. The EV-TOU-2 rate is a whole house EV rate, which has
12 different prices for each time-of-use period.⁷ EV-TOU-2 prices used in this analysis are
13 \$0.2900/kWh On-Peak, \$0.1896/kWh Off-Peak, and \$0.1651/kWh Super Off-Peak. The
14 DR rate is the default residential rate, which has inverted tier prices with four price tiers
15 determined by total consumption.⁸ The DR price used in this analysis is assumed to be are
16 \$0.264092/kWh for summer months, and \$0.298066/kWh for winter months. These DR
17 prices are weighted averages of the DR rate tiers. Fifty percent of all SF residential EV
18 charging is assumed to occur under the DR rate and 50% under EV-TOU-2.

⁷ For details on SDG&E's Schedule EV-TOU-2 *see*:
https://www.sdge.com/sites/default/files/regulatory/020114-schedule_ev-tou.pdf.

⁸ For details on SDG&E's Schedule DR *see*:
https://www.sdge.com/sites/default/files/regulatory/020114-schedule_dr.pdf

1 **3. Flat Rate**

2 The Flat Rate is intended as a generalized price for non-utility EV charging. The observed
3 price for non-utility EV charging in the SDG&E service territory is generally either free,
4 priced by the hour, or priced as a subscription for limited to unlimited charging access. The
5 Flat Rate is derived from an assumed average non-utility EV charging cost of \$1.25 per EV
6 charging hour. This cost is translated to a flat \$0.36/kWh price by assuming that non-utility
7 EV chargers dispense electricity at an average rate of 3.5 kW per connected hour.

8 **4. VGI Rate**

9 A central component to SDG&E’s proposed VGI Pilot Program is the VGI Rate: a
10 dynamic hourly electricity price that incorporates California Independent System Operator
11 (CAISO) wholesale electricity prices and Critical Peak Pricing (CPP) for the California
12 electricity system and for SDG&E distribution circuits. The VGI Rate is calculated in the
13 cost-benefit model as described in Ms. Fang’s testimony with two exceptions to
14 accommodate price modeling limitations. The two modeling exceptions are:

15 **a. CAISO Day-Ahead Hourly Price**

16 CAISO day-ahead hourly price and CAISO Day-of adjustment are estimated using
17 the hourly incremental costs of energy described in section II.D.2.

18 **b. VGI Commodity Critical Peak Pricing Hourly Adder**

19 The VGI Commodity Critical Peak Pricing (C-CPP) Hourly Adder is applied to the
20 top 150 statewide gross load forecast hours as a proxy for SDG&E top system hours. The
21 Statewide gross load forecast is used instead of SDG&E’s system load in order to remain
22 consistent with the DER Avoided Cost methodology.

1 of the year.⁹ The final step in estimating the load impacts for the entire EV market is to
2 aggregate the charging load shapes to the EV population.

3 **C. Aggregate EV Charging Impacts**

4 As discussed above, EV charging load impacts are estimated using a cost
5 optimization process to determine hourly kWh charging for the EV Driver Group locations
6 and for each EV Type. These group load shapes are allocated to the EV population forecast
7 to create aggregate charging load shapes for the EV market in SDG&E's service territory,
8 under the two scenarios. Load shapes are a key input to several components of the standard
9 cost tests discussed below.

10 **1. Allocation of EV Customer Groups to Population Forecast**

11 Each driver group is allocated to the EV Population forecast based on several factors.
12 The factors include the assumption that 46% of all current EV drivers have access to
13 workplace charging today.¹⁰ The proportion of EV charging in use at workplace and MuD
14 also are a factor in the allocation, as is the installation schedule for the workplace and MuD
15 chargers. Table 6-4 shows the allocations over time.
16

⁹ These hourly load shapes are an input to the Utility Bill and Commercial Charging Fees, as shown in section II.D.1.

¹⁰ This assumption is based on survey results from the California Center for Sustainable Energy (CCSE) February 2014 Report and Infographic, available at <http://energycenter.org/clean-vehicle-rebate-project/vehicle-owner-survey/feb-2014-survey>.

1

Table 6-4

Allocation of EV Customer Groups to VGI Forecast											
EV Customer Groups			Portion of VGI Vehicle Forecast Applied to PEV Driver Groups								
Group	Residence Type	Workplace Charging Access	2014	2015	2016	2017	2018	2019	2020	2021	2022
1	SF	Preexisting	45.2%	44.4%	42.9%	40.0%	41.0%	41.8%	42.6%	43.2%	43.9%
2	SF	Unavailable	53.1%	51.8%	48.8%	43.7%	45.3%	46.8%	48.1%	49.3%	50.3%

Total			100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

2

3

2. EV Population Forecast

4 The EV population forecast is used to aggregate the EV customer groups to the
5 entire EV market in SDG&E's service territory. The EV population forecast is based on the
6 EV adoption forecast forthcoming from the California Electrification Transportation
7 Coalition (CalETC), and is shown in Table 6-6. An additional 3,300 EVs are added to the
8 CalETC forecast to create a VGI Pilot Program EV forecast (Table 6-5), in recognition that
9 a workplace and MuD charging project of the size proposed in this application will result in
10 additional EV adoption by drivers. SDG&E assumed four incremental EV purchases due to
11 each MuD VGI Pilot Program installation and eight incremental EV purchases due to each
12 workplace VGI installation.¹¹

13 The VGI EV forecast projects an EV population below the 2025 target for zero-
14 emission vehicle in the Governor's executive order to help bring 1.5 million zero-emission
15 vehicles onto California's roads.¹² SDG&E's VGI EV forecast projects 119,526 EVs in

¹¹ EV adoption due to the presence of workplace and MuD charging is a hypothesis to be tested by SDG&E's VGI Pilot Program. Appendix B to Mr. Schimka's Testimony reveals that 67% (40 out of 57 of respondents) indicated that the presence of workplace charging influenced their EV buying decision.

¹² See Governor Brown's Executive Order (March 23, 2012), <http://gov.ca.gov/news.php?id=17463>.

SDG&E’s service territory in 2025, which represents a California-wide projection of approximately 1.3 million EVs. SDG&E’s share of the California EV market is assumed to be 9.43%.

Table 6-5

Cumulative EV Population Forecast										
Year	SDG&E's Share of CalETC PEV Forecast[1]				EV Additions [2]	VGI EV Forecast[3]				
	BEV	PHEV-10	PHEV-20	PHEV-40		BEV	PHEV-10	PHEV-20	PHEV-40	Total

[1] Source: Forthcoming "California Transportation Electrification Assessment - Phase 1 Report ", Medium Forecast - Appendix A. Table 6, CalETC - prepared by ICF International. SDG&E's share is assumed to be 9.43%.

[2] EV Additions are vehicles purchased due to a Workplace and MUD charging program, these vehicles are distributed proportionally across the CalETC forecast to create the VGI forecast.

[3] The VGI EV Forecast is used in both the Flat Rate and VGI Rate scenarios.

The VGI EV forecast is used in both the VGI Rate scenario and the Flat Rate scenario. After the group load shapes are allocated to the EV population forecast, the resulting aggregate charging load shapes for the EV market in SDG&E’s service territory are available as inputs for some of the Cost Effectiveness test components (see Section II.D).

1 This section describes the cost optimization process to estimate EV charging load
2 impacts, for the Flat Rate and the VGI Rate scenarios. Assumptions on vehicle trips and
3 charging requirements and constraints are described. The prices used in the optimization
4 process are described, including SF residential rates, the Flat Rate, and the VGI Rate. The
5 approach to estimate the VGI Rate hourly price estimates are also described. The cost
6 optimization approach uses these assumptions, requirements, constraints and prices to
7 estimate hourly EV charging load shapes for the EV Customer Groups and EV Types in
8 both scenarios (Flat Rate and VGI Rate) These load shapes are aggregated to the SDG&E
9 service territory EV population in order to derive the EV Charging Load Impacts.

10 **D. Cost-Effectiveness Test Components**

11 This section describes the methods used to calculate the Test Components used in the
12 standard Cost-Effectiveness Tests. Table 6-1 shows which Test Components are used in
13 each of the Cost-Effectiveness Tests.

14 **1. EV Customer Costs and Benefits**

15 Several test components are costs paid or benefits received by the EV customer.
16 These costs and benefits include Incremental Vehicle Cost, Utility Bills, Commercial
17 Charging Fee, Gasoline Savings, Federal Tax Credits and State Rebates. Each of these
18 components is discussed in this section.

19 **a. Incremental Vehicle Cost**

20 Incremental vehicle cost is the cost premium for a customer who purchases an EV
21 relative to an otherwise comparable internal combustion engine (ICE) vehicle. Table 6-6

1 lists the cost above a comparable ICE vehicle. This cost premium is assumed to decrease
 2 over time by 10% per year.¹³

3 **Table 6-6**

EV Cost Premium and Comparable MPG		
EV Type	MPG of Comparable ICE Vehicle	Cost Above Comparable ICE Vehicle[1]
BEV	31	\$13.5K
PHEV-10	29	\$10.9K
PHEV-20	28	\$11.3K
PHEV-40	27	\$11.8K

[1]Internal Combustion Engine (ICE). Incremental cost of EV relative to ICE vehicle is assumed to decrease over time by 10% per year.

4
 5 **b. Gasoline Savings**

6 Gasoline Savings is an avoided cost for EV drivers, since they do not need to
 7 purchase fossil fuels for ZEM driving. Gasoline Savings is estimated by multiplying
 8 estimated gallons of gasoline displaced by electric fuel by a gasoline price of \$4.318 per
 9 gallon.¹⁴ The gallons of gasoline displaced are estimated by multiplying the annual ZEM
 10 requirements for each EV type by the miles per gallon (MPG) of the comparable ICE
 11 vehicle (See Table 6-6). The MPG for comparable ICE vehicles increases over time to
 12 reflect improving fuel economy requirements.

¹³ See ICF International and E3, California Transportation Electrification Assessment (Draft Phase 1 Report), March 14, 2014.

<http://www.energy.ca.gov/2009publications/CEC-600-2009-001/CEC-600-2009-001-SD.PDF>
 (see table 4, retail gasoline and diesel price forecasts, the mid-point of the High and Low values are used)

c. Utility Bills & Flat Rate Fees

Utility Bills are costs paid by the EV customer to SDG&E for charging an EV under an applicable retail rate. Utility Bills and Flat Rate Fees are estimated using load shape shares associated with the applicable rate. Applicable SDG&E Residential Rates (EV-TOU-2 and DR) are applied to load shape shares from locations using Residential Rates.¹⁵

Flat Rate Fee price is applied to load shape shares from locations using the Commercial Charging Fee price. These Flat Rate Fee load shapes are used to calculate Utility Bills for these locations. At Flat Rate Fee locations, the EV customer pays the Flat Rate Fee price, and another entity pays the Utility Bill for the electricity used for EV charging. The entity paying the Utility Bill at the Flat Rate Fee locations may be the Utility customer at that site or may be the non-utility EV charging facility owner. The Utility Bills at these Flat Rate Fee locations are assumed to be on SDG&E’s Schedule AL-TOU. The rates for the AL-TOU bill are summarized in Table 6-7.

Table 6-7

Commercial AL-TOU Rate Values Used For VGI Utility Bill Estimates					
Season	Energy (\$/kWh)			Demand (\$/kW)	
	On-Peak	Semi-Peak	Off-Peak	On-Peak	Non-Coincident
Summer	\$0.11100	\$0.08856	\$0.06539	\$ 15.57	\$ 19.96
Winter	\$0.10638	\$0.09674	\$0.07201	\$ 6.45	\$ 19.96

EV charging load shape shares are estimated during the cost optimization process and are inputs to the estimation process (*see* section II.C.2).

¹⁵ See Table 6-2 where Pricing Scenario is Residential Rates or VGI Rate or Flat Rate Fee.

d. Federal Tax Credit

The federal tax credit is a one-time tax credit available to an EV Customer who purchases a new EV. The credit amount is dependent on the battery capacity of the EV. The BEV credit is \$7,500, the PHEV-10 credit is \$2,500, the PHEV-20 credit is \$1,500 and the PHEV-10 credit is \$1,500. This credit is reduced over time for future EV purchases.¹⁶

e. State Rebate

The state rebate is a one-time payment to an EV Customer who purchases or leases a new EV. The rebate is dependent on the battery capacity of the EV. The BEV rebate is \$2,500, and the rebate for all PHEVs is \$1,500. This rebate is reduced over time for future EV leases or purchases.

2. Electricity Supply Costs

Estimated hourly incremental Electricity Supply Costs (\$/kWh) are modeled hourly using the E3 Distributed Energy Resources (DER) Avoided Cost methodology.¹⁷ The Electricity Supply Costs are a consolidation of individual cost components similar to those estimated in the DER Avoided Cost model (i.e., Energy, Losses, Ancillary Services, Emissions, Capacity, T&D, RPS) with some VGI-specific variations; each component's methodology and VGI-specific variations are described as follows.

¹⁶ See ICF International and E3, California Transportation Electrification Assessment (Draft Phase 1 Report), March 14, 2014.

¹⁷ See E3's Distributed Energy Resources Avoided Cost Model (July 24, 2012): https://www.ethree.com/documents/DERAvoidedCostModel_v3_9_2011_v4d.xlsm

1 the eight day types selected to reflect combinations of gross load conditions (high or low)
 2 and renewable generation conditions (high or low). Each day type was assigned a weight,
 3 such that the eight day types can be combined to represent a full year. This energy price
 4 component replaces the DER model's energy price.

5 **Table 6-8**

REFLEX Model Day Types						
Day Type	Descriptive Month	Day of Week	Load Level	Renewable Availability	Days Per Year	% Weight
1	March	Weekday	Low	High	37	10.1%
2	March	Weekend	Low	High	30	8.2%
3	July	Weekday	High	High	26	7.1%
4	September	Weekday	High	Low	24	6.6%
5	September	Weekend	High	Low	1	0.3%
6	August	Weekday	High	High	57	15.6%
7	November	Weekend	Low	Low	73	20.0%
8	December	Weekday	Low	Low	117	32.1%
					365	100.0%

6
 7 **b. Losses**

8 In addition to energy prices, incremental energy losses are estimated.²³ Losses are
 9 calculated from the DER avoided cost model using SDG&E's time of use-specific
 10 transmission and distribution loss factors. Losses are applied as a fraction of the incremental
 11 energy price. This approach reflects that EV loads at the meter require a larger amount of
 12 central station generation (and corresponding carbon emissions) due to energy losses.

13 **c. Ancillary services costs**

14 Incremental ancillary service (such as scheduling, dispatch, reactive power, voltage
 15 control, loss compensation, load following, system protection, and energy imbalance) are the

²³ Losses are caused by electrical resistance; resistance increases with electric load.

1 same as in the DER avoided cost model; ancillary services cost was assumed to be 1% of
2 hourly energy cost.

3 **e. System Capacity Costs**

4 Annual system capacity values are derived from the DER avoided cost model. The
5 annual values are allocated to individual hours using the methodology applied in the DER
6 avoided cost model, which assigns incremental system capacity values to the top 250 hours
7 of net load over the course of the year. As in the DER avoided cost model, a planning
8 reserve margin of 15% is included. The Resource Balance Year is adjusted from 2017 to
9 2014 to reflect the fact that SDG&E is currently authorized to procure additional generation
10 capacity.²⁴

11 **f. T&D Capacity Costs**

12 In the DER avoided cost model, annual transmission and distribution (T&D) deferral
13 values are allocated to specific hours based on climate-zone specific temperatures. Hourly
14 allocation factors from that model represent California climate zone 7, as defined by the
15 California Energy Commission.²⁵ Climate zone 7 is the best match to SDG&E's service
16 territory.

17 **g. RPS Cost**

18 The incremental RPS factor is applied to hourly incremental Energy Cost to reflect
19 the additional renewable resources that must be purchased by the utility as a result of load
20 increases, under a 33% and a 40% renewables level considered in the analysis. These RPS
21 factor estimates are taken directly from the DER avoided cost model.

²⁴ See D.14-03-004, pp. 2 and 4.

h. Total Electricity Supply Cost Estimates

2

3

4

5

6

7

8

9

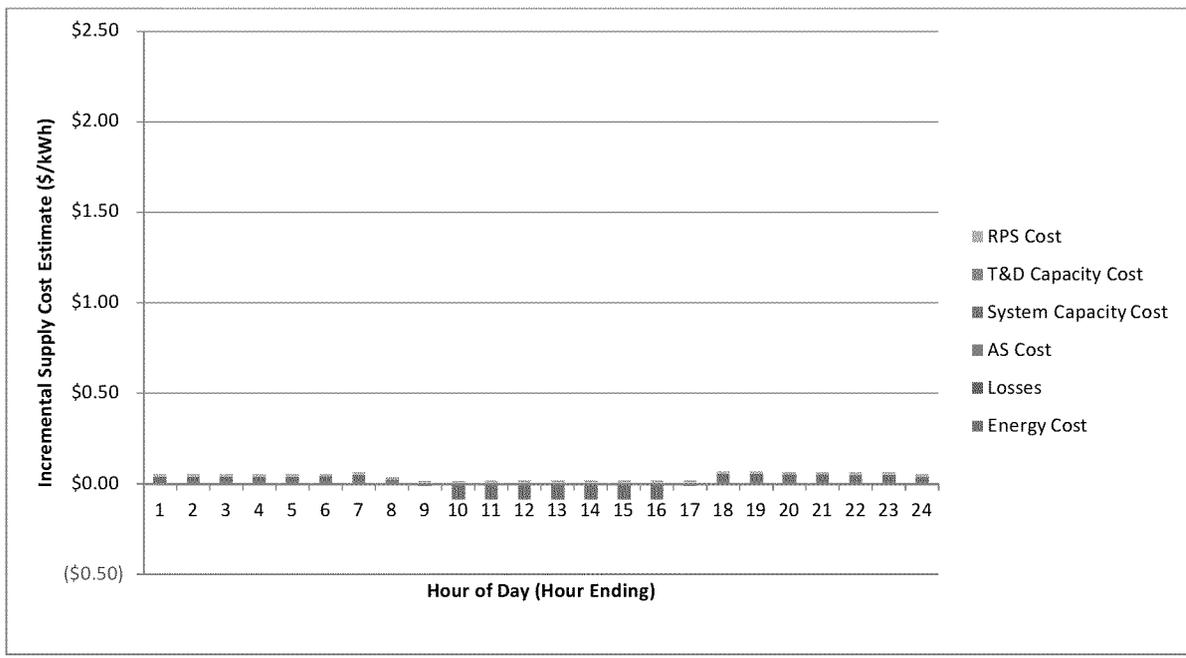

10

11

12

The incremental hourly Electricity Supply Cost estimates are the sum of each of the hourly components described previously. Hourly Electricity Supply Cost estimates were developed for each of the eight representative day types. As described, each day type was assigned a weight such that the eight days combined to result in a year of hourly Electricity Supply Costs and extrapolated into the future using the E3 NEM Avoided Cost Model methodology. This estimate is used as the Electricity Supply Cost (\$/kWh) component of the standard cost test. Examples of the estimated hourly Electricity Supply Cost estimates for two day types are illustrated in Figures 6-1 and 6-2.

3. EV Charging Equipment Costs and Administrative Costs

5

6

7

8

9

10

11

12

13

14

Charging Equipment costs and Administrative costs for the VGI Rate scenario are the VGI Pilot Program costs described in Mr. Schimka's testimony and quantified in Mr. Atun's testimony. Table 6-9 defines which costs in Mr. Schimka's testimony are applicable to Charging Equipment costs and which are applicable to Administrative costs. Table 6-9 also indicates which costs are applicable to the Flat Rate scenario. VGI Billing costs are excluded from the Flat Rate scenario (see shaded cost components in Table 6-9). Franchise Fees and Uncollectables (FF&U) are removed from the Flat Rate scenario cost estimates since FF&U do not apply to a non-utility owner EV charger.

Table 6-9

VGI Pilot Program Costs Standard Cost Test Treatment by Market Expansion Scenario				
Mr. Schimka's Testimony Cost Components		Cost Test Treatment

6.F.a	Customer Support and Billing Integration Services	Administrative	Yes	No
6.G.a	Rates/Distribution Circuit Modeling	Administrative	Yes	No
6.H.a	Evaluation of VGI Program & Load Impacts	Administrative	Yes	Yes

Charging Equipment costs at SF residences (included in both scenarios) are assumed to be dependent on the type of EV. BEVs and PHEV-40 are assumed to have L2 SF residence chargers at a cost of \$1,500 per EV, and PHEV-10 and PHEV-20 are assumed to have the L1 cord set provided with the EV at no incremental cost.

Pre-existing workplace charging equipment cost is estimated at \$1,500 per EV charger. The number of preexisting workplace charging units is estimated at 0.2 per EV in

1 service.²⁶ Pre-existing workplace charging equipment is assumed to be the same for both
2 scenarios (VGI Rate scenario and Flat Rate scenario).

3 **4. Societal Benefits**

4 SDG&E includes three sets of societal benefits for use in the Societal Cost Test.
5 These societal benefits are Avoided Gasoline CO₂, Low Carbon Fuel Standard (LCFS)
6 Credits, and Criteria Pollutants. Mr. Krevat's testimony describes how California law and
7 policy promotes these beneficial measures in the public interest.²⁷ In theory, Avoided
8 Gasoline CO₂ and Low Carbon Fuel Standard (LCFS) Credits benefits are also EV Customer
9 Benefits, but since these markets are so new and the future market value attributable to them
10 is not well understood, and uncertainty to whom the benefits will ultimately accrue, they are
11 considered Societal Benefits in this analysis.

12 **a. Avoided Gasoline CO₂**

13 Avoided Gasoline CO₂ is the value of avoided CO₂ similar to the value of Gasoline
14 Savings. Avoided Gasoline CO₂ value is estimated using the gasoline gallon estimate in the
15 Gasoline Savings (discussed above) multiplied by the Carbon Cost included in Electricity
16 Supply Costs.

17 **b. LCFS Benefits**

18 LCFS Benefits, per the California Air Resources Board (CARB), are the value of
19 LCFS credits earned and sold by a utility related to selling electricity as a transportation
20 fuel. LCFS Benefits are estimated based on the ZEM associated kWhrs.

14
15

c. Criteria Pollutants

Criteria Pollutants include Greenhouse Gases (GHG), Nitrous Oxides (NOx), Particulate Matter (PM) and Volatile Organic Chemicals (VOC).²⁸ These criteria pollutants are avoided when gasoline is displaced by electric fuel. Results from the forthcoming CalETC report are used to estimate these criteria pollutant benefits based on the calculated Gasoline Savings (see section II.D.1)

III. COST EFFECTIVENESS TESTS

The illustrative results presented include standard costs test. Each cost test is designed to answer a key policy question relating to the EV market development. Table 6-10 describes the key questions answered for each of the Cost-Benefit Tests.²⁹ The cost tests are: Ratepayer Impact Measure (RIM), Participant Cost Test (PCT), Total Resource Cost (TRC), and Societal Cost Test (SCT). These tests are intended to quantify the costs and benefits of SDG&E market level EV adoption and charging. These tests are performed for both the VGI Rate scenario and the Flat Rate scenario.

²⁸ ICF International and E3, California Transportation Electrification Assessment (Draft Phase 1 Report), March 14, 2014.

²⁹ See “Understanding Cost-Effectiveness of Energy Efficiency Programs: Best Practices, Technical Methods, and Emerging Issues for Policy-Makers” (2008) Table 2.2, available at <http://www.epa.gov/cleanenergy/documents/suca/cost-effectiveness.pdf>

1

Table 6-10

Cost -Benefit Tests - Key Questions Answered		
Cost Test	Acronym	Key Question Answered
Ratepayer Impact Measure	RIM	Will utility rates increase?
Participant Cost Test	PCT	Will the participants benefit over the measure life?
Total Resource Cost	TRC	Will the total costs of energy in the utility service territory decrease?
Societal Cost Test	SCT	Is the utility, state, or nation better off as a whole?

2

3 IV. ILLUSTRATIVE COST EFFECTIVENESS

4 The illustrative results from the cost effectiveness model for the two scenarios
5 analyzed are summarized below. Illustrative results are presented at the total SDG&E
6 service territory market level for EV charging, for both scenarios as well as relative to each
7 other. Illustrative results are reported at the 40% renewables level, and sensitivity analysis
8 also provides results at the 33% renewables level.³⁰ Relative results highlight the net benefit
9 or net costs of the VGI Rate scenario compared to the Flat Rate scenario (*see* section II.A.1
10 above for descriptions of the two scenarios).

11 Results are reported as the Net Present Value (NPV) for costs and benefits between
12 2015 and 2028. NPV discount rate is 6.76%, representing SDG&E's after tax weighted
13 average cost of capital. Tax rates are assumed to be 35% Federal and 8.84% State.
14 Arguably, a societal discount rate could be used for the SCT, however for simplicity the
15 SDG&E WACC is used.

16

³⁰ See section II.D.2.a for discussion on the two RPS levels.

1 The illustrative results in Table 6-11 show that both scenarios provide market level
2 net benefits in all four cost-effectiveness tests. The VGI Rate scenario estimated net
3 benefits, ranging from \$124.6 million NPV benefits for the Rate Payer Impact test to \$460.1
4 million NPV benefits for the Societal Cost Test. The Table 6-11 illustrative results are
5 market level net benefits for the entire SDG&E service territory EV population. These
6 illustrative results indicate that the SDG&E service territory EV market is beneficial to
7 SDG&E ratepayers (RIM), EV customers (PCT), and the SDG&E service territory region in
8 general (TRC and SCT).

9 In relative terms, the VGI Rate scenario provides the SDG&E service territory region
10 an estimated \$13.1 million NPV impact greater than the Flat Rate scenario for both the TRC
11 test and the SCT. The VGI Rate scenario provides SDG&E's EV customers an estimated
12 \$20.3 million more NPV impact in the PCT, compared to the Flat Rate scenario. The RIM
13 test is positive for both the VGI Rate and Flat Rate scenario, showing that incremental
14 revenues from utility bills exceed the market level electric supply costs to serve EV
15 charging, as well as, charger costs and administration costs. However, the VGI Rate scenario
16 has an estimated \$61.1 million less NPV impact for ratepayers than the Flat Rate scenario in
17 the RIM test.

18 The RIM test result is mainly due to the fact that VGI charger infrastructure is owned
19 by SDG&E and Administrative cost incurred by SDG&E are a cost to ratepayers and
20 therefore are included in the RIM test. The Flat Rate scenario charger infrastructure and
21 administrative costs provided by a non-utility entity (third party) are absorbed by the non-
22 utility owners of the equipment, as opposed to ratepayers, and therefore not included in the
23 RIM test result.

1 If the Flat Rate scenario were funded by ratepayers (directly or indirectly), then the
 2 non-utility entity's costs should be included the RIM test. The non-utility entity (third party)
 3 costs are estimated at \$72.0 million NPV, for charger infrastructure and administrative
 4 costs. Adding \$72.0 million NPV to the Flat Rate scenario RIM would result in a positive
 5 VGI Net Impact of approximately \$10.9 million NPV (versus the negative VGI Net Impact
 6 of \$61.1 million NPV report in Table 6-11).

7 **Table 6-11**

Cost Effectiveness Tests - Illustrative Results (NPV \$ Millions)				
Scenario	Cost Effectiveness Test			
	RIM	PCT	TRC	SCT
VGI Rate	\$124.6	\$290.7	\$264.7	\$460.1
Flat Rate	\$185.8	\$270.4	\$251.5	\$447.0
VGI Net Impact	(\$61.1)	\$20.3	\$13.1	\$13.1
VGI % of Flat	67%	108%	105%	103%

8
 9 Illustrative detail results are provided in Table 6-12. Table 6-12 provides illustrative
 10 detailed cost and benefit results for each test component, by cost effectiveness test and
 11 scenario. The table also summarizes the total costs and total benefits for each cost-
 12 effectiveness test, as well as the Cost/Benefit (C/B) Ratio. A C/B Ratio greater than 1.0
 13 indicates that total estimated benefits are greater than total estimated costs.
 14

13

14

15

Table 6-13 provides a sensitivity table of the estimated net TRC for the VGI Rate scenario, relative to the Flat Rate scenario. The sensitivity is for two analysis components, Renewables Penetration and Pilot Charger Utilization. Renewables Penetration is the level of renewables generation included in the energy cost model estimates (*see* section II.D.2.a). Renewable Penetration sensitivities are 33% and 40%. Pilot Charging Utilization is the number of EVs that utilize the EV charging equipment at workplace and MuD locations on a given day. The Pilot Charging Utilization used in the two scenarios and included in the results is one EV charged at each workplace and MuD charger each day (base case). The sensitivity analysis considers Pilot Charging Utilization of 1, 1.5 and 2 EV(s) charging per day. The sensitivity analysis shows even at the 33% Renewables Penetration and base case Pilot Charger Utilization, the VGI Rate scenario has an estimated \$1.7 million NPV benefits greater than the Flat Rate scenario.

1

Table 6-13

Net TRC Cost Effectiveness - Illustrative Sensitivity (VGI Rate scenario - Flat Rate scenario) (NPV \$ Millions)			
Renewables Penetration	Pilot Charger Utilization (EVs per Charger per Day)		
	1	1.5	2
33%	\$1.7	\$2.4	\$3.1
40%	\$13.1	\$16.3	\$18.3

Table 6-14 provides cost component details for the Electricity Supply Costs. The table shows that the VGI Rate scenario results have lower estimated Electricity Supply Costs for all components. The VGI Rate scenario has lower estimated Energy Costs by over \$14 million NPV, has lower estimated Capacity Cost by almost \$4 million NPV, and has lower estimated T&D Costs by about \$1 million NPV, than the Flat Rate scenario. Total Electric Supply Costs for the Flat Rate scenario is an estimated \$20.3 million NPV higher than the VGI Rate scenario.

10

Table 6-14

Electricity Supply Costs - Illustrative Component Results (NPV \$ Millions)		
Cost Components	Market Scenario	
	VGI Rate	Flat Rate
Energy Cost	\$175.1	\$189.5
Losses	\$13.6	\$14.6
A/S Cost	\$1.8	\$1.9
Capacity Cost	\$35.9	\$39.7
T&D Cost	\$14.8	\$15.7
RPS Cost	\$46.7	\$46.7
Total Elec. Supply Costs	\$287.8	\$308.1

11

1 Table 6-15 provides illustrative Electricity Supply Costs sensitivity results for the
 2 VGI Rate scenario relative to the Flat Rate scenario. The sensitivities considered in Table 6-
 3 15 are the same as Table 6-13 (Renewables Penetration and Pilot Charger Utilization).
 4 Results show that the estimated Electric Supply costs for the VGI Rate scenario are less than
 5 the Flat Rate scenario by \$8.9 to \$25.4 million NPV over the sensitivity ranges.

6 **Table 6-15**

Electricity Supply Costs - Illustrative Sensitivity (VGI Rate scenario - Flat Rate scenario) (NPV \$ Millions)			
Renewables Penetration	Pilot Charger Utilization (EVs per Charger per Day)		
	1	1.5	2
33%	\$ (8.9)	\$ (9.5)	\$ (10.2)
40%	\$ (20.3)	\$ (23.4)	\$ (25.4)

7
 8 **V. RESEARCH PLAN – DATA COLLECTION AND ANALYSIS**

9 The Research Plan described below provides a link between the hypothesized
 10 assumptions described in section I and results illustrated in section IV. The realized VGI
 11 Pilot Program results will be available upon completion of the VGI Pilot Program. As
 12 customer EV charging data and cost information becomes available through the VGI Pilot
 13 Program deployment and operation, observed results will replace hypothesized assumptions
 14 used above in order to more rigorously evaluate the cost-effectiveness of SDG&E's
 15 completed VGI Pilot Program. Data collection will begin the first year of the pilot (2015),
 16 load impact analysis and reporting will begin after two years of implementation (2017), and
 17 a cost-effectiveness analysis 18 months after the final VGI facility is installed (2019).

18 SDG&E will perform a cost-effectiveness analysis eighteen months after the last
 19 VGI facility is installed and operational, using the data gathered during the VGI Pilot

1 Program. SDG&E will report the results of the analysis to the Commission and interested
2 parties. This time frame allows six months for SDG&E to analyze at least one year's data
3 for each VGI facility. The following data collection and analysis is planned for the VGI

4 Pilot Program:

- 5 • Actual VGI installation costs (total and average per site);
- 6 • Actual VGI operating costs (over the fleet of VGI facilities);
- 7 • Charging load profiles (from the VGI facility metered data for MUD and
8 workplace locations, in aggregate and by circuit);
- 9 • Estimated percentage of EV purchases related to the VGI Pilot Program
10 (gathered through surveys of EV customers using the VGI facilities);
- 11 • Estimated VGI Pilot program-related increases in ZEV miles traveled per EV
12 (gathered through surveys of EV customers using the VGI facilities);
- 13 • EV customer input on the VGI mobile and web applications, the VGI rate
14 and overall convenience and ease of use of the VGI facility (gathered through
15 surveys of EV customers using the VGI facilities);
- 16 • VGI kWh usage by price, over time (gathered through the SDG&E VGI
17 billing data);
- 18 • Where available, EV related kWh usage at home will be reviewed with VGI
19 kWh usage at workplace VGI facilities (gathered through the SDG&E VGI
20 billing data); and
- 21 • Where possible, determine whether EV-TOU or EV-TOU2 adoption has
22 increased as a result of the VGI Pilot.

1 SDG&E intends to conduct measurement and evaluation studies on the VGI Pilot
2 Program. If, after two years of implementation, the extent to which the VGI Pilot Program
3 produces load impacts, load impact studies will be conducted according the Load Impact
4 Protocols that were adopted in D-08-04-051. These protocols provided rules that specified
5 required output data that must be included in all measurement and evaluation reports. For
6 example, these protocols require that every load impact measurement and evaluation report
7 include hourly ex-post load impact results for each event day for the entire program, as well
8 as on average per customer. In addition, each load impact report is required to contain a 10-
9 year hourly forecast of expected future load impacts for 24 different temperature scenarios.
10 D-08-04-051 further required that every demand response activity be evaluated every year
11 and that the load impact reports be filed with the CPUC on April 1st of each year.³¹ The
12 decision specified that the load impact protocols applied to all demand response activities,
13 which includes both demand response programs and dynamic rates.

14 **VI. CONCLUSION**

15 Illustrative results presented in my testimony indicate that the EV charging market in
16 SDG&E's service territory with the VGI Pilot Program provides net benefits. The
17 illustrative results indicate that the SDG&E service territory EV market with the VGI Pilot
18 Program is beneficial to SDG&E ratepayers, EV customers, and the SDG&E service
19 territory region in general.

20 This concludes my direct testimony.

21
³¹ CPP and dynamic rates are considered Demand Response activities.

1 **VII. STATEMENT OF QUALIFICATIONS**

2 My name is John C. Martin. My business address is 8306 Century Park Court, San
3 Diego, California 92123. I am employed by San Diego Gas & Electric Company as Project
4 Manager in Clean Transportation.

5 I have over 21 years of energy industry experience. My current duties involve
6 project management to support SDG&E's electric transportation efforts, including EV rates,
7 market participant support and implementing a pilot using third party EV submetering with
8 utility subtractive billing. Prior duties focus on costs and benefits associated with the
9 capabilities of Smart Metering and Home Area Networks, and conservation based
10 information feedback. This work draws upon my broad experience in the electricity and oil
11 industry.

12 My prior electricity work experience includes demand response program and tariff
13 development, electricity trading and scheduling, demand side management program
14 evaluation and load research of customer energy use. My duties also utilize my experience
15 in the oil trading, refining and marketing industries.

16 My electric vehicle driving experience began in 1997. I currently lease a PHEV-20,
17 as of January 2013. I actively charge my vehicle at home, at my workplace, and at
18 commercial facilities. I am a member of an electric car sharing service.

19 My education is in the general area of resource economics. I graduated from Cornell
20 University in 1988 with a master's degree in agricultural economics. My Bachelor of
21 Science degree was granted by Purdue University in 1984 in business and farm
22 management. I have previously testified before the California Public Utilities Commission
23 in the SDG&E AMI and the SoCalGas AMI proceedings.

APPENDIX A

GLOSSARY OF ACRONYMS AND DEFINED TERMS

ACRONYM	TERM
Base Miles	ZEM for EV customer groups without access to workplace charging
Base+ Miles	ZEM for EV customer groups with access to workplace charging
BEV	Battery electric vehicle
Cal ETC	California Electrification Transportation Coalition
Charging Fee	Commercial charging fee
Day/Night Hours	For purposes of the study, day hours are 8 AM to 5 PM, and night hours are 6 PM to 7 AM
DER	Distributed energy resources
DG	Distributed generation
DR	Demand responses
E3	Energy and Environmental Economics (consulting firm)
EE	Energy efficiency
EV	Electric vehicle
ICE	Internal combustion engine
LCFS	Low carbon fuel standard credits
MuD	Multi-unit dwelling
O&M	Operations and maintenance
PAC	Program administrator cost
PCT	Participant cost test
PEV	Plug-in electric vehicles
PHEV	Plug-in hybrid electric vehicles
PHEV-10	Plug-in hybrid electric vehicle with 10 mile EV range

PHEV-20	Plug-in hybrid electric vehicle with 20 mile EV range
PHEV-40	Plug-in hybrid electric vehicle with 40 mile EV range
REFLEX	Renewable energy flexibility model
RIM	Ratepayer impact measure
RPS	Renewable portfolio standard
RTP	Real-time pricing
SCT	Societal cost-test
SF	Single family
SOC	State of charge
T&D	Transmission and distribution
TRC	Total resource cost-test
VGI	Vehicle-grid integration
VGI Rate	Dynamic time-variant prices
ZEM	Zero emission miles
